

ABSTRACT**LOCATING ITEMS**

5 A mobile telecommunications device (10, 12, 14, 16) has both short
range, piconet, telecommunications ability and long range cellular
telecommunications ability. Mobile items of personal property, eg a pair
of glasses (18) can be lost by an individual. The telecommunications
10 devices (10, 12, 14, 16) keep an activity log of the times of existence and
members of piconets of which they have been members. If a lost item
(18) is not in the present piconet (26) of a user's device (10) it can
backtrack through its activity log to find the last piconet for which both it
and the missing item (18) were members, and can identify from the
activity log what other devices (12, 14, 16) were present in that particular
15 piconet. The device (10) can then contact the devices (12, 14, 16) and
determine whether the missing item 18 is presently part of their piconet,
and hence can locate the missing item if it is present in one of their
piconets. The device may also geostamp its activity records and/or be
aware of its geographical position.
